Male breast carcinoma is an uncommon phenomenon, accounting for less than 1% of all malignancies of the breast. The approximate annual incidence in Europe is 1 in 100,000 cases. The highest incidence occurs 5-10 years later in men than in women, with a peak at 60 to 67 years of age. We here describe a case of male breast carcinoma in a young patient (44 years of age), which is quite unusual in the pattern of breast carcinoma presentation.

Key words: case report, intraoperative radiotherapy, male breast cancer, nipple-sparing mastectomy.
