ABSTRACT

Molecular imaging of receptors expressed on the surface of tumor cells is becoming a major field of investigation in clinical oncology, especially for the detection of cancer at its earliest stages. Nowadays, MRI, microcomputed tomography (microCT), ultrasound, positron emission tomography (PET), optical coherence tomography (OCT), and other major imaging systems are available to scientists and clinicians. Each technique has advantages and limitations, thus making them complementary. We report herein our investigations on the synthesis and use of new probes for small animal imaging as well as on the preparation and use of targeting complexes to deliver specific gene in tumors cells.

Key words: tumor, targeting, carbon nanotubes, optical imaging, nanoparticles, folate, in vivo imaging.

Acknowledgments: We thank Dr Bich-Thuy Doan (ICSN, CNRS, UPR 2301, Gif sur Yvette, France) for the MRI experiments, J. Seguin (UPCG, CNRS UMR 8151, Paris, France) for all the in vivo experiments on small animals, C. Chanec, S. Malrejean and M. Bessodes for their contribution to the work described in part II19 and Dr. Pierre Wils, and H. Hofland for their contribution to the work described in part IV22 of this communication.
